Lab 0 (It Contains COREA Design)

It consists of MBIST, Synthesis, Scan (with out wrappers), ATPG, Simulations.

```
MemoryTemplate (SYNC_1R1W_16x8) { // {{{

    MemoryType          : SRAM;  // PG mandatory
    CellName            : SYNC_1R1W_16x8;
    Algorithm           : SMarchCHKBvcd;
    BitGrouping         : 1;
    //ShadowWrite         : On;
    //ShadowWriteOK       : On;
    //ShadowRead          : On;
    //ReadOutofRangeOK    : On;
    TransparentMode     : SyncMux;
    //DataOutStage        : None;
    OperationSet        : Sync;
    LogicalPorts        : 1R1W;
```

Sync Mux means adding a logic to bypass the memory
So memory has to be bypass during Scan, ATPG, EDT and tool will add a logic to bypass the memories

```
1 #//
2 #//      ---  |   |     /\       ----   ----              /|
3 #//     |   | |   |    /  \    |      |                  / |

5 #//     |     |   |  /------\       | |      ========     |
6 ##//    |     |   | /        \  ----   ----              __|__
7
8
9 ### context "dft rtl" tell the tool to enter into RTL insertion mode, design_id tells to create a seperate directory in t
  sdb for this particular below insertion steps. -design_id <your custom name for this insertion , for example first_insert
  ion>
10 set_context dft -rtl -design_id first_insertion
11
12 ## specify the output directory where you want to dump the outputs of mbist insertion
13 set_tsdb_output_directory ../tsdb_outdir
14
15 ## provide the design files and library files
16 read_cell_library ../../library/adk.tcelllib
17
18 read_verilog ../../library/mems/SYNC_1R1W_16x8.v -exclude_from_file_dictionary -verbose
19
20 read_verilog ../design/corea.v -verbose
21
22 ## Elaborate the design
23 set_current_design corea
24
25 # set the design level to either chip, physical_block or sub_block
26 set_design_level physical_block
27
28 ## declare the clocks and constraints
29 add_clocks 0 clka -period 10ns
30 add_clocks 0 clkb -period 13.2ns
31 ##add_clocks 0 clkc -period 14ns
32
33 set_dft_specification_requirements -memory_test on
34
35 #//
```

Line 10: Inside the tsdb output directory a sub-directory with this design id will be created and all the outputs with this particular run it will be stored into that particular directory

Line13: By default it will be created in current directory, so our current directory is MBIST Insertion. But for complete lab0 to have common tsdb output directory

Line 16,18,20: Reading the library files, the memory file and the corea we are reading.

Line 23: Setting the current design of corea and it will do elaboration, it will check whether all the module definition is available or not and whether module instantiation is correct or not.

Line 26: set_design_level physical_block

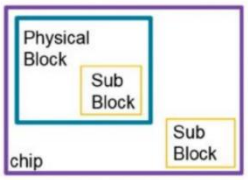
Where DFT is Inserted?

COMMAND :
set_design_level

Physical Block :
It is a layout region
Layout of this region is done separately and the module boundary will exists after the layout is done.

Sub Block :
The hierarchy of the sub block netlist may not exist after layout and gets merged with its parent.

Chip :
It is a layout region
Required ports for DFT need to exist and be connected to IO pads.



NOTE :
The design level will be decided by Design Team, DFT Team and the PD team together.

Line 33: -memory_test on means we are doing MBIST Insertion and if we -logic_test on means we are doing EDT and OCC Insertion.

Whatever the test hardware has inserted into MBIST insertion run that will be included into the dft specification

Specifying DFT Requirement

- Specifies the requirements to be checked during ***check_design_rules***.

Command : ***set_dft_specification_requirements -memory_test on***

- "-memory_test on" option is needed when implementing memory test.
- When memory_test on, memory_bist, memory_bisr_chains, and memory_bisr_controller default to auto; otherwise they are default to off.
- When memory_bist option is set to auto, if the current design contains memories, the MBIST pre-DFT DRC rules will be checked during *check_design_rules* command. The required specifications will also be included to the DFT specification when the command *create_dft_specification is executed*.

```
35 #//
36 #//      ---  |   |     /\       ----   ----            ----
37 #//     |   | |   |    /  \     |      |                   |
38 #//     |_ _| |- -|   /    \     ----  |----   ========   __/
39 #//     |     |   |  /------\         | |     ========  |
40 #//     |     |   | /        \  ----   ----              ------
41
42 ## DFT Signals
43 #add_dft_signal ltest_en int_mode ext_mode tck_occ_en int_ltest_en ext_ltest_en // should be enabled if we go for wrapper
   s in scan
44 add_dft_signal ltest_en
45 add_dft_signal scan_en   -source_node scan_en
46 add_dft_signal shift_capture_clock -source_node test_clock
47
48
49 check_design_rules
```

Line 44: Only static signals can be controlled by TDR

Line 45: Scan Enable will be controlled by the top level ports scan enable.
Source node that is scan_en will be controlled by top level port i.e. scan_en

Line 46: Shift capture clock it will be controlled by the top level port test clock

So we will run till line 49 in tessent tool

```

62 process_dft_specification
63
64 ## Till above command, tool will be in insertion state, giving below command will make the tool to shift to setup state
65 extract_icl
66
67 stop
```

Line 59: creat_dft_specification

DFT Specification

- The DFT Specification describes the test hardware that will be added to your design.
  - IJTAG Network configuration
  - Memory BIST partitioning/configuration

    Memory BIST partitioning :
    - Listing of Memory BIST controllers to be generated.
    - Clock domain associated with each memory BIST controller.
    - Memories assigned to each controller.

All the above information will be coming in dft specs.

Creating a New DFT Specification

- A new DFT Specification can be created using the command ***create_dft_specification***
- This command uses information from prior settings :
  - set_design_level
  - Design netlist etc

For example for IJTAG Network:-

Viewing a DFT Specification

Command : *report_config_data*

```
DftSpecification(corea,first_insertion) {
  IjtagNetwork {
    HostScanInterface(ijtag) {
      Sib(sri) {
        Attributes {
          tessent_dft_function : scan_resource_instrument_host;
        }
        Tdr(sri_ctrl) {
          Attributes {
            tessent_dft_function : scan_resource_instrument_dft_control;
          }
        }
      }
      Sib(sti) {
        Attributes {
          tessent_dft_function : scan_tested_instrument_host;
        }
        Sib(mbist) {
        }
      }
    }
  }
```

IJTAG Network

So in IJTAG network 3 SIBS will be created and 1 TDR SRI Control

Inside 3 SIBS

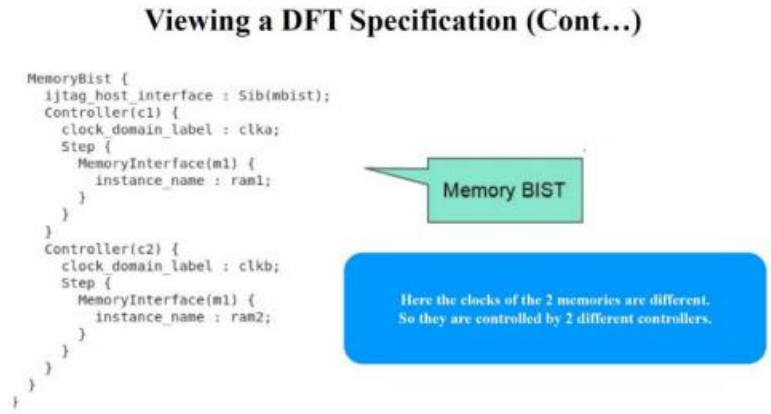
- SIB STI (Scan Tested Instrument)

- SIB SRI (Scan Resource Instrument)
- SIB MBIST - It will only controls the MBIST Network

TDR SRI control

- This TDR (As of now it will controlling the once signal that is entest enable signal) but later in lab3 we will insert some more static signals like memory bypass enable, TCK OCC Enable, MBIST enable,

This are the things will be inserted during IJTAG Network



In this above code clka is going to ram1 and clkb is going to ram2, that is memory grouping so because of both this stamps having 2 different clocks.
So, both this clocks it has 2 different clocks and 2 different controllers.

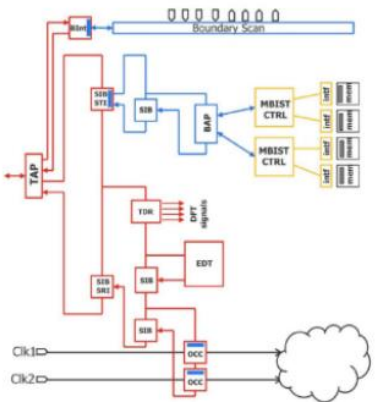
```
ANALYSIS> create_dft_specification
//
//  Begin creation of DftSpecification(corea,first_insertion)
//    Creation of RtlCells wrapper
//    Creation of IjtagNetwork wrapper
//    Creation of MemoryBist wrapper
//    Creation of MemoryBisr wrapper
//
//  Done  creation of DftSpecification(corea,first_insertion)
//
/DftSpecification(corea,first_insertion)
```

```
ANALYSIS> report_config_data

DefaultsSpecification(user) {
}
DftSpecification(corea,first_insertion) {
  IjtagNetwork {
    HostScanInterface(ijtag) {
      Sib(sri) {
        Attributes {
          tessent_dft_function : scan_resource_instrument_host;
        }
        Tdr(sri_ctrl) {
          Attributes {
            tessent_dft_function : scan_resource_instrument_dft_control;
          }
        }
      }
      Sib(sti) {
        Attributes {
          tessent_dft_function : scan_tested_instrument_host;
        }
        Sib(mbist) {
        }
      }
    }
  }
  MemoryBist {
    ijtag_host_interface : Sib(mbist);
    Controller(c1) {
      clock_domain_label : clka;
      Step {
        MemoryInterface(m1) {
          instance_name : ram1;
        }
      }
    }
    Controller(c2) {
      clock_domain_label : clkb;
      Step {
        MemoryInterface(m1) {
          instance_name : ram2;
        }
      }
    }
  }
}
```

This the Network which the tool will be created

Diagrammatic Representation of DFT Specification



- A SIB is a special node in IJTAG that acts as a switch.
- Instruments that needs to be active during scan (EDT OCC) are inserted under 1 SIB and the ones that are scan tested such as MBIST controller are inserted under another SIB.

Types of SIBS

Scan Tested Instrument (STI) : The SIB STI provides access to the IJTAG network for MBIST controller (in this fig).

Scan Resource Instrument (SRI) : The SIB SRI provides access to the IJTAG network for logic instruments (EDT, OCC)

Difference between SIB - STI and SIB - SRI

And why are telling as a switch?

- Because It will decide whether to allow or not to allow the data to be return on to the TDR that's why SIB acts as a switch.

Instruments that need to be active during scan they are placed under one SIB and the instruments that has to be scan tested that is MBIST Controller It will be scanned tested and they will be placed under another SIB.

Line 62: It will validate whatever HW it has generated on top and it will inserted in our design and it will finally write out all the output files into the TSDB output directory.

Generating and Inserting the Hardware

Command : *process_dft_specification*

- Validates the DFT Specification
- Generates hardware : MBIST related controllers, memory interfaces, IJTAG network
    - RTL and ICL descriptions
- Edits design and inserts generated hardware
- Generates SDC constraints
- Generated files are written into TSDB directory

Line 65: extract_icl

```
ANALYSIS> process_dft_specification
//
//  Begin processing of /DftSpecification(corea,first_insertion)
//    --- IP generation phase ---
//    Validation of IjtagNetwork

st_c1.generation_log,
//           ../tsdb_outdir/instruments/corea_first_insertion_mbist.instrument/corea_first_insertion_tessent_mbi
st_c2.generation_log
```

```
//      Generating design files for Bist Access Port
//
//      Loading the generated RTL verilog files (5) to enable instantiating the contained modules
//      into the design.
//      Generating design files for MemoryBist controller assemblies
//    --- Instrument insertion phase ---
//   Inserting instruments of type 'ijtag'
//   Inserting instruments of type 'memory_bist'
//
//    Writing out modified source design in ../tsdb_outdir/dft_inserted_designs/corea_first_insertion.dft_insert
ed_design
//    Writing out specification in ../tsdb_outdir/dft_inserted_designs/corea_first_insertion.dft_spec
//
//  Done  processing of DftSpecification(corea,first_insertion)
//
/DftSpecification(corea,first insertion)
```

So it was validating the design, whatever DT HW it has generated and it is inserting in our design and it is also writing all the output files into the tsdb output directory so individually for all the sibs, sri control tdr, verilog files and ICL description and even MBIST also, and control it will be creating individually all the three sibs.

```
INSERTION> extract_icl

//  Begin circuit learning analyses.
//  --------------------------------
//  Learning completed, CPU time=0.00 sec.
//  ------------------------------------------------------------------------
//  Begin ICL extraction.
//  ---------------------
//  ICL extraction completed, ICL instances=11, CPU time=0.10 sec.
//  ------------------------------------------------------------------------
//  ------------------------------------------------------------------------
//  Begin ICL elaboration and checking.
//  -----------------------------------
//  ICL elaboration completed, CPU time=0.08 sec.
//  ------------------------------------------------------------------------
//  Writing ICL file : ../tsdb_outdir/dft_inserted_designs/corea_first_insertion.dft_inserted_design/corea.icl
//  Writing consolidated PDL file: ../tsdb_outdir/dft_inserted_designs/corea_first_insertion.dft_inserted_design
/corea.pdl

//  Writing SDC file: ../tsdb_outdir/dft_inserted_designs/corea_first_insertion.dft_inserted_design/corea.sdc
//  Writing DFT info dictionary: ../tsdb_outdir/dft_inserted_designs/corea_first_insertion.dft_inserted_design/c
orea.dft_info_dictionary
```

So the ICL, PDL, SDC File all these files will be created.

It will be check in the tsdb output directory

So, corea files will be created.

```

75
76 #create_patterns_spec
77 set spec1 [create_patterns_spec]
78
79 report_config_data $spec1
80
81 ## This will start creating the patterns which are required for mbist/sib network
82 process_patterns_specification
83
84
85 ## This command will prepare the RTL file list to be read in synthesis tool ( DC supportive)
86 write_design_import_script -use_relative_path_to . -replace
87
```

Line 77: It will create the patterns specs. And what is pattern specs?
It is similar to TCL command.

```
SETUP> set spec1 [create_patterns_spec]
//  sub-command: create_patterns_specification
//  Creating '/PatternsSpecification(corea,first_insertion,signoff)'
//    Getting patterns specifications for the 'ijtag' instrument type
//    Getting patterns specifications for the 'memory_bist' instrument type
/PatternsSpecification(corea,first_insertion,signoff)
```

Line 79: Whatever it store into spec1 variable that we will able to see.

$spec1 means what all are the dollar specifications which has created that we will get in this terminal.

```
SETUP> report_config_data $spec1

PatternsSpecification(corea,first_insertion,signoff) {
  AdvancedOptions {
    ConstantPortSettings {
      scan_en : 0;
    }
  }

            compare_go_id : on;
          }
        }
      }
    }
```

```
  }
  Patterns(MemoryBist_ParallelRetentionTest_P1) {
    ClockPeriods {
      clkb : 13.2ns;
      clka : 10.0ns;
    }
    TestStep(ParallelRetentionTest) {
      MemoryBist {
        run_mode : hw_default;
        parallel_retention_time : 0;
        reduced_address_count : on;
        Controller(corea_first_insertion_tessent_mbist_c1_controller_inst) {
          parallel_retention_group : 1;
          DiagnosisOptions {
            compare_go_id : on;
          }
        }
        Controller(corea_first_insertion_tessent_mbist_c2_controller_inst) {
          parallel_retention_group : 1;
          DiagnosisOptions {
            compare_go_id : on;
          }
        }
      }
    }
  }
}
```

Pattern Specification (Contd…)

reduced_address_count : on ; → Enables the MBIST controller to run on 4 corners of the common memory address space.
This is useful to check the proper functionality of the BIST controller without having to simulate the test for the entire memory space.
This is reduce the run time.

```
TestStep(run_time_prog) {
  MemoryBist {
    run_mode : run_time_prog;
    reduced_address_count : on;
    Controller(corea_first_insertion_tessent_mbist_c1_controller_inst) {
      DiagnosisOptions {
        compare_go : on;
        compare_go_id : on;
      }
    }
```

reduced_address_count : on (This is done before manufacturing validation)

Pattern Specification (Contd..)

GO bit indicates whether the controller has passed/failed the simulation.
It indicates the comparator's pass/fail status.

When the test starts, the GO bit starts high and falls when a comparator fails (BIST controller received erroneous response from the memory) and stays low till the end of the test.

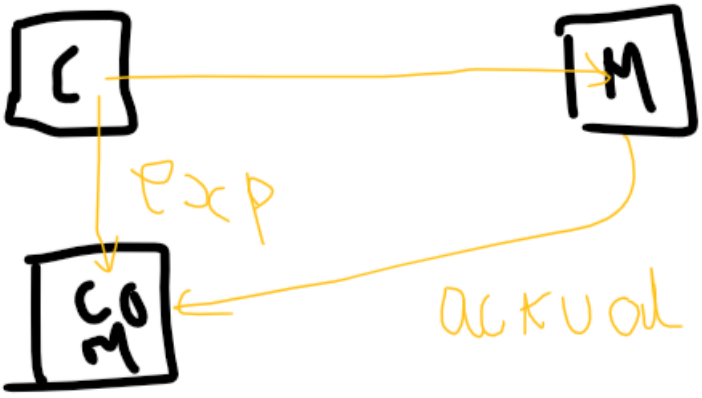
At the end of the test,
if GO is 1'b1, it indicates no failing memories
if GO is 1'b0, it indicates detection of failing memories.

```
TestStep(run_time_prog) {
  MemoryBist {
    run_mode : run_time_prog;
    reduced_address_count : on;
    Controller(corea_first_insertion_tessent_mbist_c1_controller_inst) {
      DiagnosisOptions {
        compare_go : on;
        compare_go_id : on;
      }
    }
```

If compare_go is on, then it will check the GO bits.

FSM and signal which is present inside the controller.

1. so it will write a value memory which is present inside a controller (0 is written onto a memory)
2. Same value will be write it out into a comparator.



3. Output of the memory will be given to the comparator and it will be checked.

- If both are same, comparator will be expected value and output of the memory will be actual value, then the go bit will be high only.
- If suppose coupling fault is there in memory, 0 has got change to 1, then we got erroneous message in memory when both these things are compared then go bit will go low and it will stay low thoughout the test.

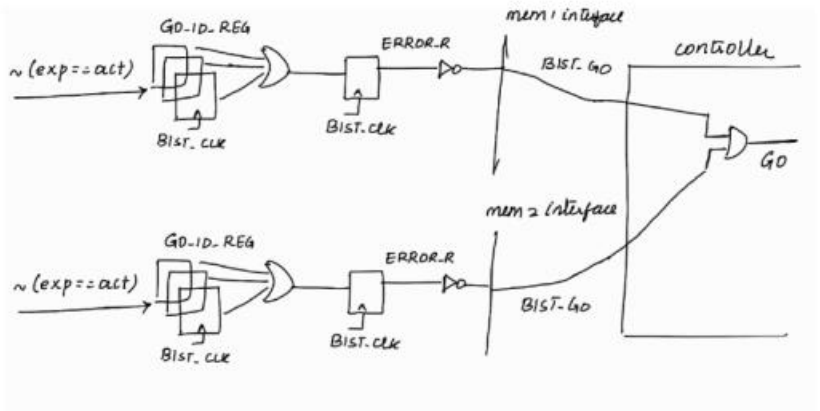
Pattern Specification (Contd..)

When compare_go_id is set to on, we can directly get from the simulation logfile the failing controllers, the ICL and design instance of the memory interface and go_id_reg of the failing memory.

When compare_go_id is set to off, the only information which we get from the simulation logfile is the failing controller.

```
TestStep(run_time_prog) {
  MemoryBist {
    run_mode : run_time_prog;
    reduced_address_count : on;
    Controller(corea_first_insertion_tessent_mbist_c1_controller_inst) {
      DiagnosisOptions {
        compare_go : on;
        compare_go_id : on;
      }
    }
```

- If some memories are failing then the simulation log file will tell which controller is failing and then ICL and design instance of the memory interface and go id ref of the failing memory, if compare go id is turned on.



- Expected value is written to the comparator, and actual value from the memory that is actual patterns that is output value from the memory ~(exp == act) it's a relational operator

- The number of bits of the go id reg it will be equal to the number of dout in the memory.
- If a single controller it is controlling more than one memory where it will be there in memory grouping concept, the BIST_GO which is specific for 1st memory and for 2nd memory again I will be having another BIST_GO, so this two things, it will inside the controller it will be added and the output will be GO.

Line 82: It will validate all the patterns specifications and it will finally write out the TB and patterns files into the tsdb output directory/patterns directory.

```
SETUP> process_patterns_specification
//
//  Begin processing of /PatternsSpecification(corea,first_insertion,signoff)
//
//    Processing of /PatternsSpecification(corea,first_insertion,signoff)/Patterns(ICLNetwork)
//
//      Creation of pattern 'ICLNetwork'
//        Solving ICLNetworkVerify(corea)
//
//      Writing pattern file '../tsdb_outdir/patterns/corea_first_insertion.patterns_signoff/ICLNetwork.v'
//
//    Processing of /PatternsSpecification(corea,first_insertion,signoff)/Patterns(MemoryBist_P1)
//      Processing of TestStep(run_time_prog) instrument 'memory_bist'
//
//      Creation of pattern 'MemoryBist_P1'
//        Solving TestStep(run_time_prog)
//
//      Writing pattern file '../tsdb_outdir/patterns/corea_first_insertion.patterns_signoff/MemoryBist_P1.v'
//
//    Processing of /PatternsSpecification(corea,first_insertion,signoff)/Patterns(MemoryBist_ParallelRetentionT
est_P1)
//      Processing of TestStep(ParallelRetentionTest) instrument 'memory_bist'
//
//      Creation of pattern 'MemoryBist_ParallelRetentionTest_P1'
//        Solving TestStep(ParallelRetentionTest)
//
//      Writing pattern file '../tsdb_outdir/patterns/corea_first_insertion.patterns_signoff/MemoryBist_Parallel
RetentionTest_P1.v'
//      Writing simulation data dictionary file '../tsdb_outdir/patterns/corea_first_insertion.patterns_signoff/
simulation.data_dictionary'
//
//  Done  processing of /PatternsSpecification(corea,first_insertion,signoff)
//
//  Writing configuration data file '../tsdb_outdir/patterns/corea_first_insertion.patterns_spec_signoff'.
```

Line 86: After MBIST Insertion we are not having here EDT and OCC insertion, directly we will do synthesis, then tool will directly write out the RTL file list which has to be read into the synthesis whichever files has to be inputs of synthesis that will be automatically written out by the tool.

```
SETUP> write_design_import_script -use_relative_path_to . -replace
//  Writing file 'corea.dc_shell_import_script'.
```

```
87
88 #//
89 #//      ---  |   |     /\       ----   ----            ----

94
95
96 ## We can invoke the simuation tool via mentor tessent inorder to perform simulations in same shell/session.
97
98 ## if we want to provide any additional library files which are in verilog format that are supported in simulator
99 set_simulation_library_sources -v ../../library/adk.v -y ../../library/mems -extension v
100
101 report_simulation_library_sources
102
103 ## This command will create the  setup/compilation/simulation command files automatically supported by all tools and also
     exceutes them
104 #run_testbench_simualtions -<options> ; default it will write questa supportive files
105 run_testbench_simulations
106
```

Line 99: Whichever the library file we want to read during simulation time i.e. adk.v library file we are reading and then inside this mems directory whichever having file is .v extension inside the mems directory those files will be read that is the verilog file of the memory.

Line 101: Whatever the library it has been read that will be displayed here.

```
SETUP> set_simulation_library_sources -v ../../library/adk.v -y ../../library/mems -extension v
SETUP> report_simulation_library_sources
//
//  List of -v/-y files and directories
//  type  path                                                                  file extensions
//  ----  ------------------------------------------------------------------    ---------------
//  file  ../../library/adk.v
//  dir   ../../library/mems                                                     v v.gz
//  file  /home/tools/mentor/MENTOR SOURCE/lnx-x86/lib64/hdleng/lib/dft sim.v
```

Inside the mems, whatever having the .v extension those files will be read. It describes the functionality of the memory

Line 105: run test bench simulations

- It will automatically do the sims scripts and it will tell the status

```
SETUP> run_testbench_simulations
Starting 3 simulations for ./simulation_outdir/corea_first_insertion.simulation_signoff
//  Waiting for the simulation(s) to complete

unscheduled 0 queued 0 running 0 pass 3 fail 0
```

The 3 simulations are:

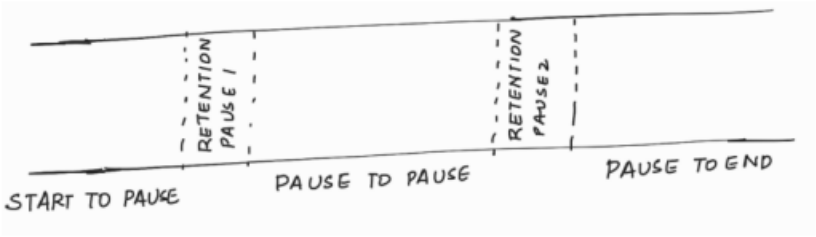
- One is to validate the IJTAG-ICL network
- One is to validate the MBIST network
- One is to validate the Memory Retention Test Network

So all the simulations has been passed

RETENTION TEST

Retention Test is done to check if the memory cells are able to retain the value for some time.
So instead of reading immediately after a cell is written, we pause it for some time and then read the memory.

Step	Event	Library Algorithm Phase Execution
1	Load checkerboard background	start_to_pause
2	Apply first retention pause	n/a
3	Read checkerboard background. Load inverse checkerboard background.	pause_to_pause
4	Apply second retention pause	n/a
5	Read inverse checkerboard background	pause_to_end



Step 1: Start to pause phase: tool will load the checkerboard algorithm, It means alternatively 0's and 1's will be return.

Step 2: Apply first retention pause

Step 3: Whatever the checkerboard pattern is written here that will be read, and the inverse checkerboard pattern will be loaded. Like 1st for Black Cells in station it is representing like 1 is written then all white cells 0 is written that is checkerboard pattern.
Inverse Checkerboard pattern it is just the opposite that is black cells 0 will be written, and for white cells 1 will be written.

Step 4: Apply second retention pause

Step 5: Inverse checkerboard pattern will be read.

- **So this is what happens in memory retention test. This is retention test, to check if the memory cells we are able to retain the value for sometime or not. So instead of reading the memory immediately after it has written we will read the memory after some time.**
- **So write the memory pause it for sometime and afterwards will read the memory.**

Extracting till ICL

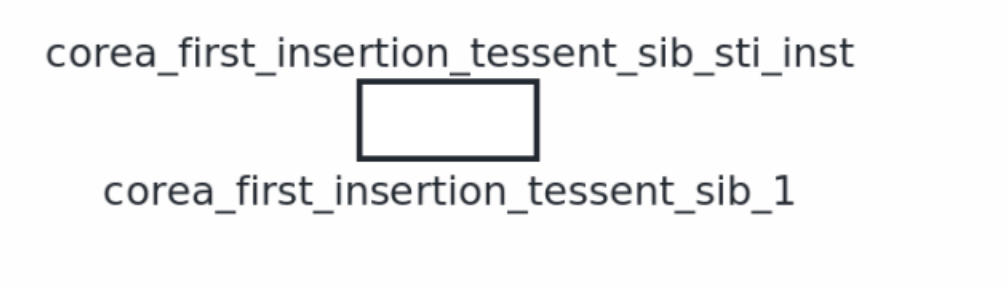
```
64 ## Till above command, tool will be in insertion state, giving below command will make the tool to shift to
   setup state
65 extract_icl
66
67 stop
```

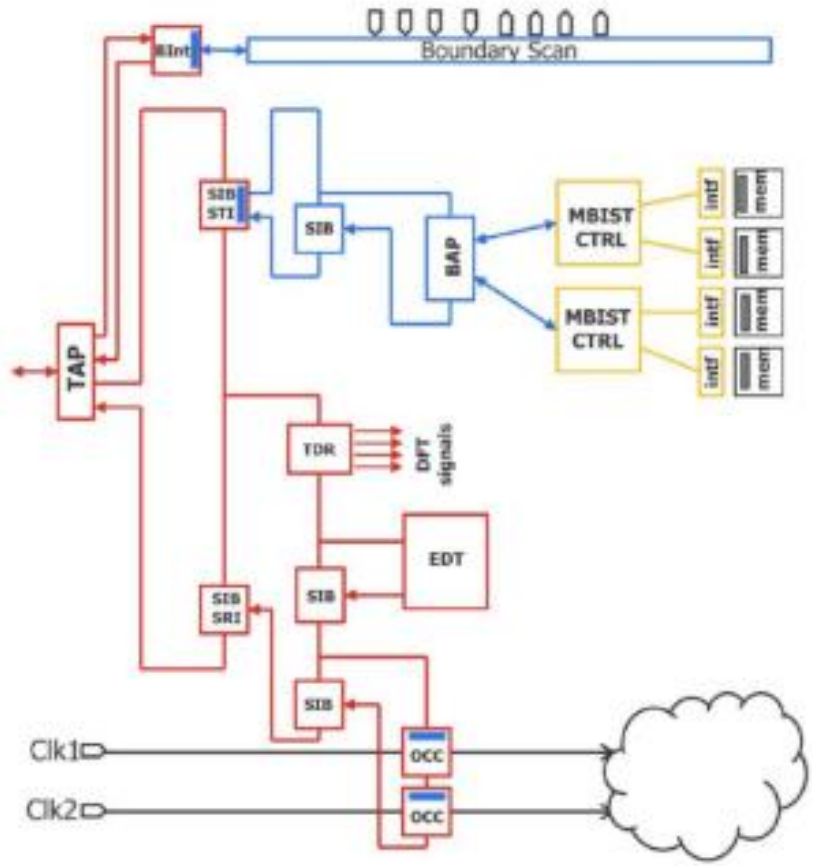
To get the complete path

```
SETUP> get_instance *sib* -hier
{corea_first_insertion_tessent_sib_mbist_inst corea_first_insertion_tessent_sib_sri_inst corea_first_insertion_t
essent_sib_sti_inst corea_first_insertion_tessent_mbist_bap_inst/corea_first_insertion_tessent_mbist_controller_
sib_ctl_bypass_inst corea_first_insertion_tessent_mbist_bap_inst/corea_first_insertion_tessent_mbist_controller_
sib_inst0 corea_first_insertion_tessent_mbist_bap_inst/corea_first_insertion_tessent_mbist_controller_sib_inst1
corea_first_insertion_tessent_mbist_bap_inst/corea_first_insertion_tessent_mbist_controller_sib_tdr_bypass_inst}
```

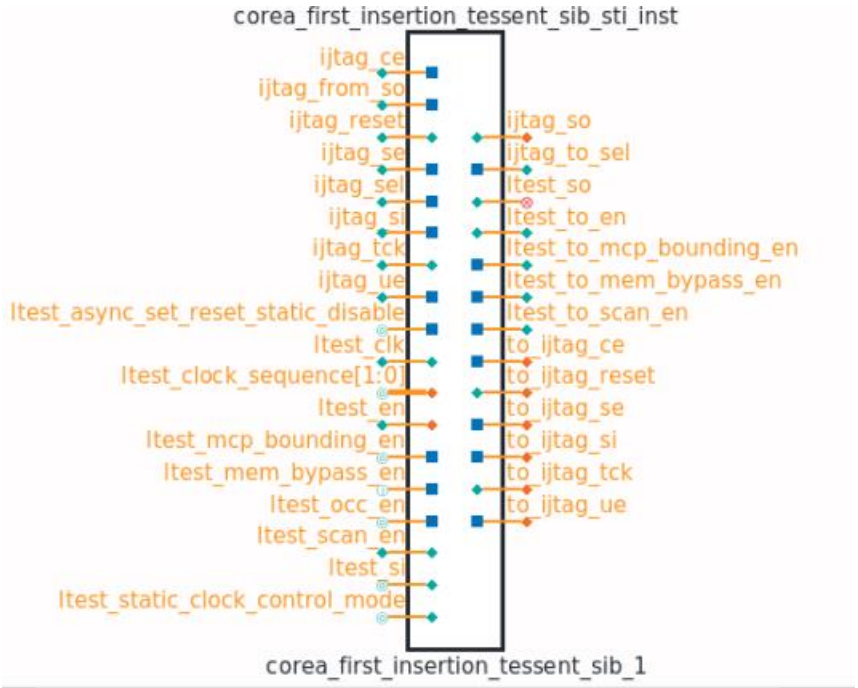
Add schematic objects in 2021 version and it was similar to add display instances in the 2016 tessent version

```
SETUP> a_s_o corea_first_insertion_tessent_sib_sti_inst -disp hier
```

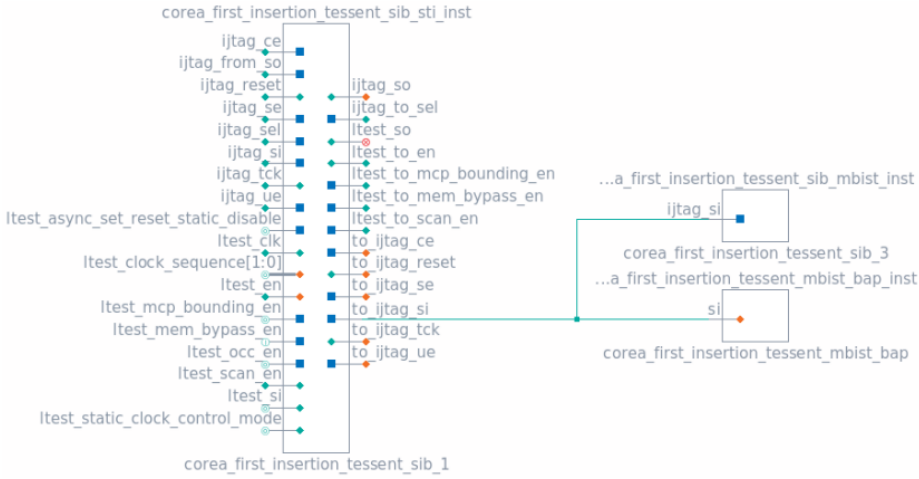




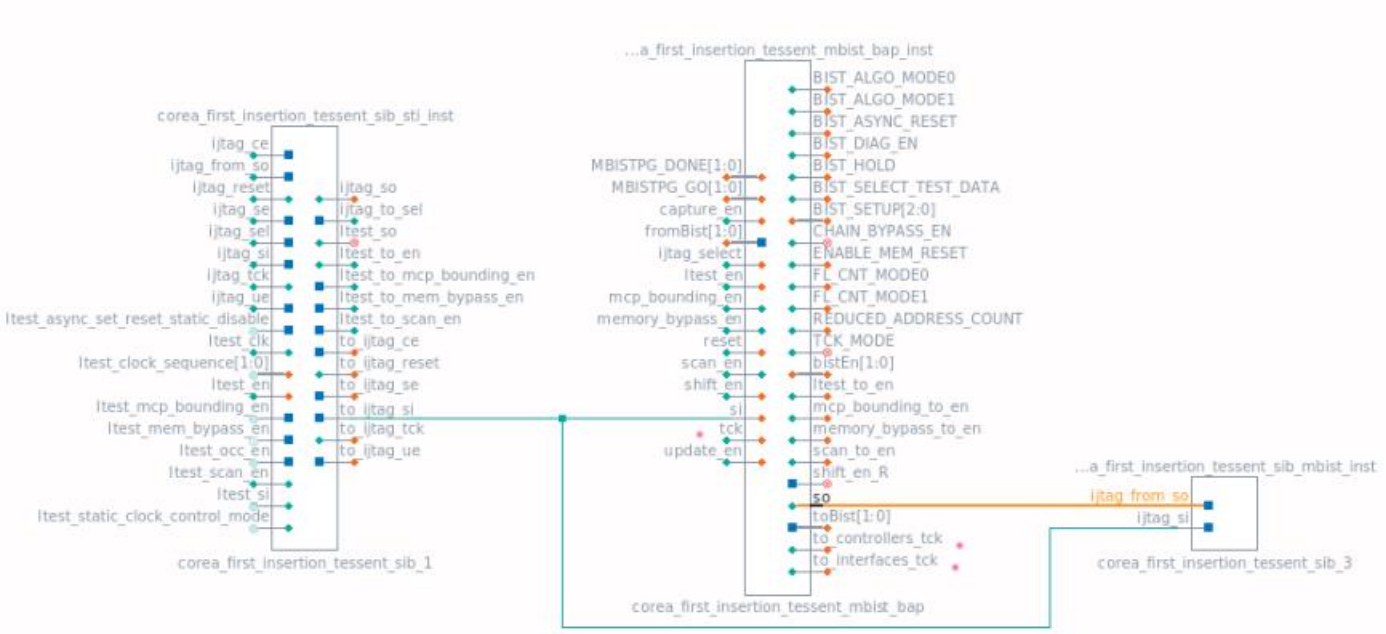
```
SETUP> a_s_o corea_first_insertion_tessent_sib_sti_inst -disp hier
```



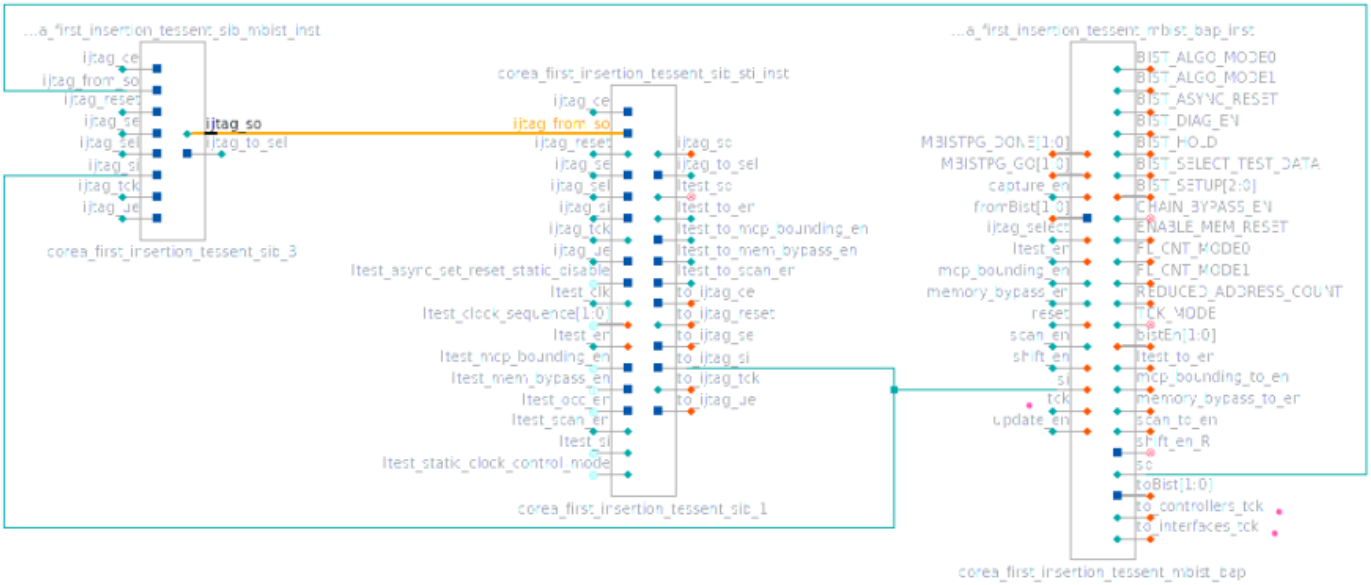
1. IJTAG to SI it will be going to SIB MBIST and another fanout will be going to BAP



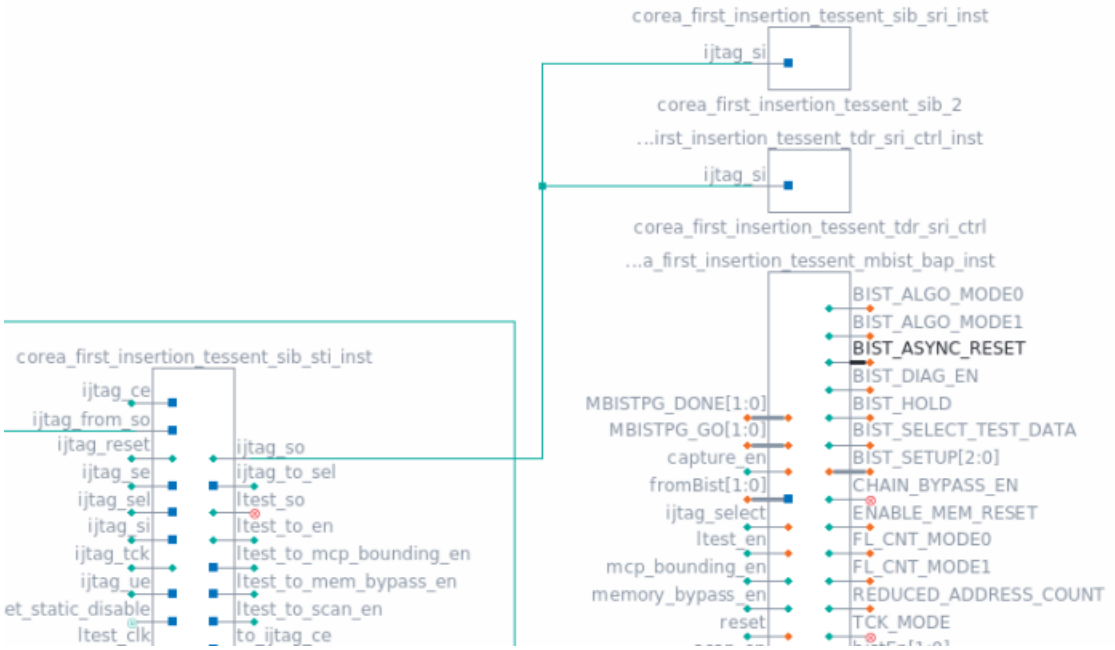
2. BAPS output it will got SIB MBIST



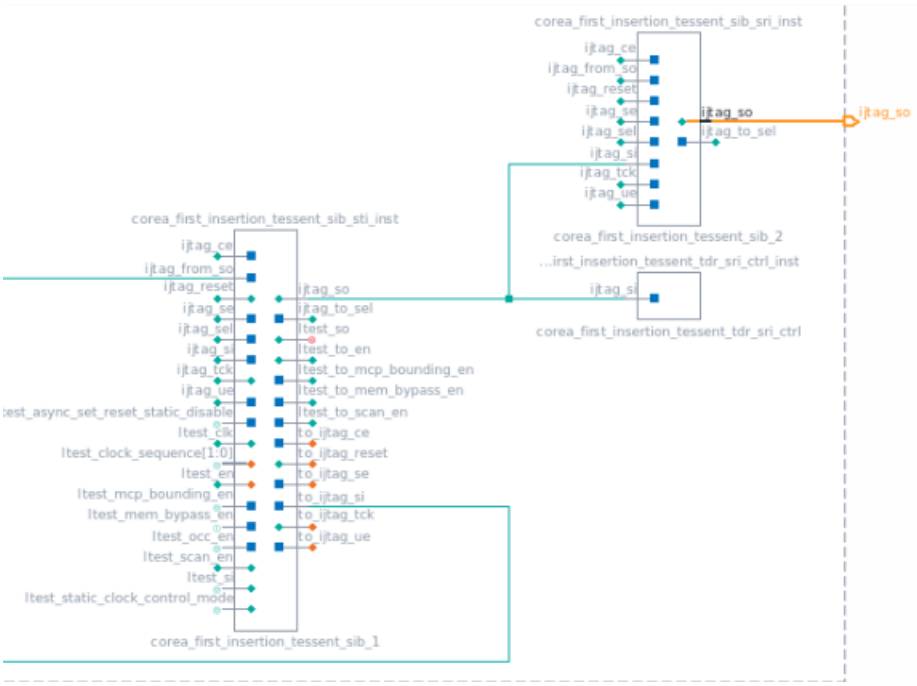
3. SIB MBIST it will go SIB STI



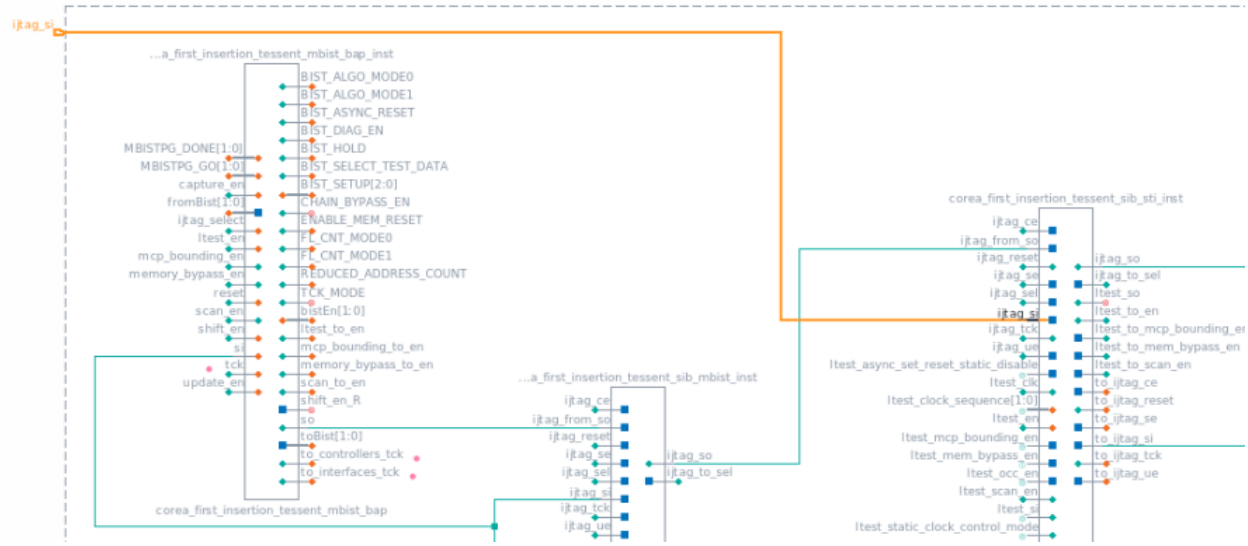
4. SIB STI Output will go SIB SRI and another fanout will go to TDR



5. SIB SRI output will go to Top level Port, but later if we go in COREB level it will controlled by another SIB

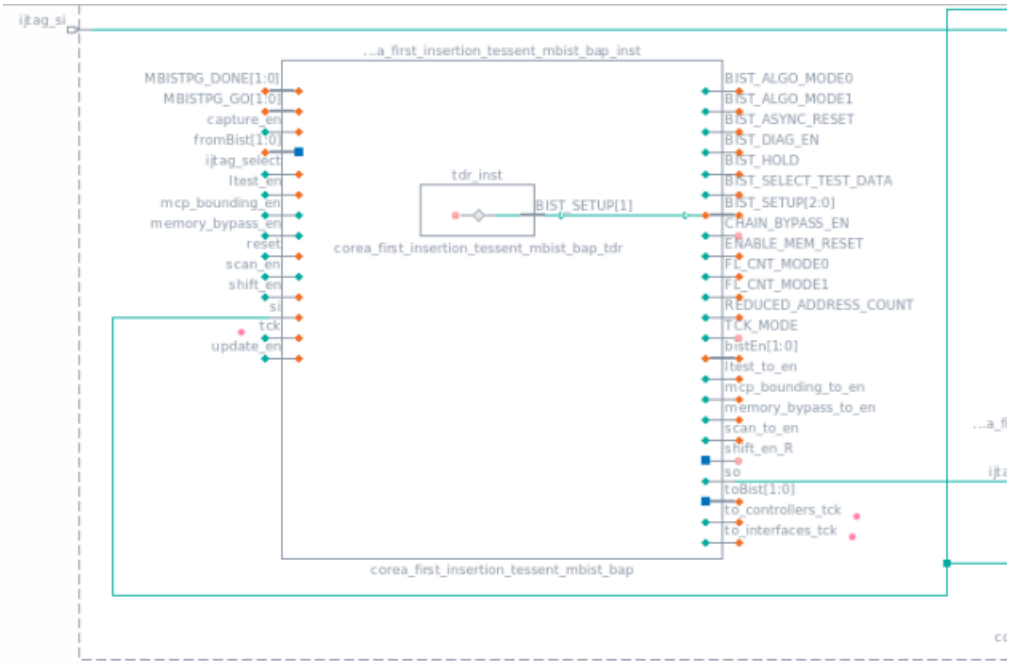


6. SIB STI Input is coming from IJTAG Design which is a TOP level port but later if we go for COREB level, it will be controlled by another SIB.

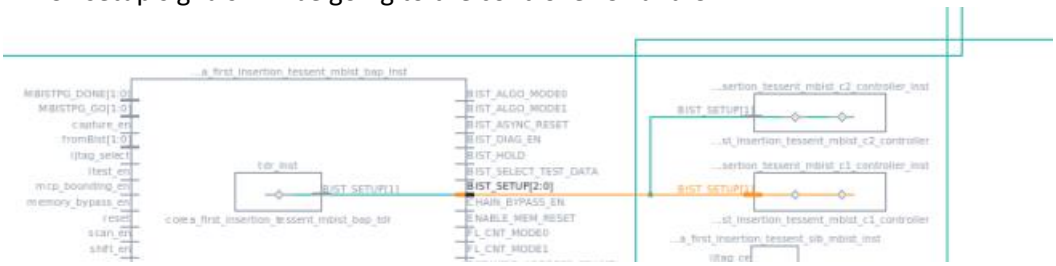


7. Inside the BAP it has a TDR logic, so the output of BAP will be controlling the signals

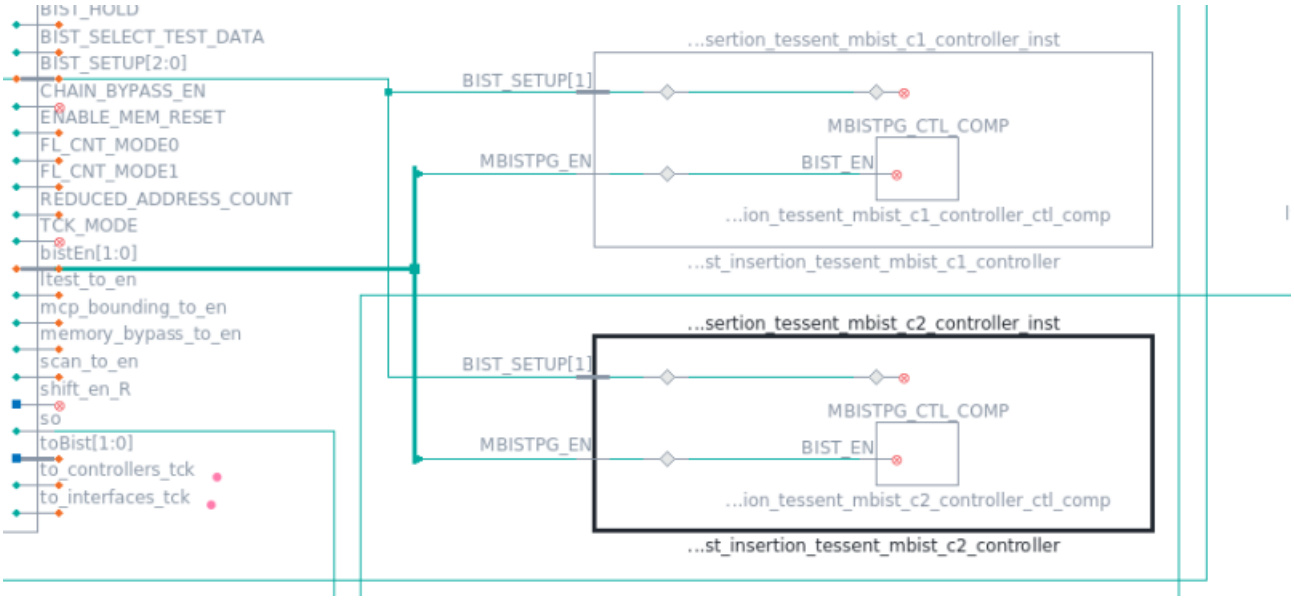
- It requires MBIST PG Enable, MBIST Setup signal, these signals has to be controlled in order to start the MBIST operation, these signals will be controlled by BAP so it has TDR inside a BAP that will be controlling the signals.



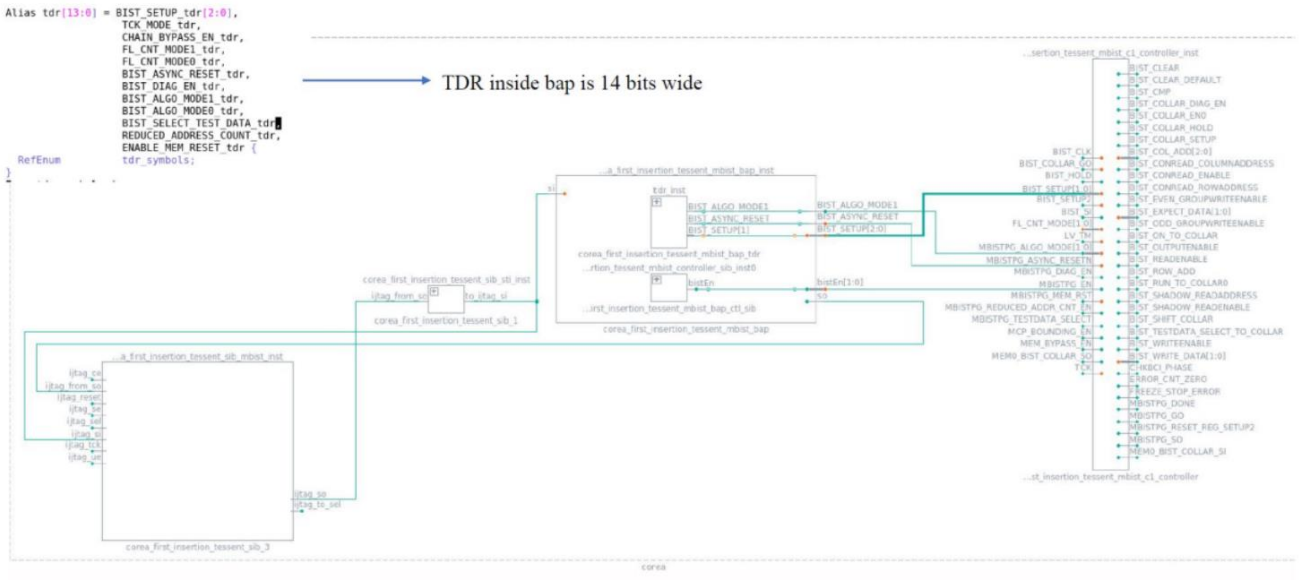
- BIST setup signals will be going to the controller C1 and C2



8. BIST Enable signal will be controlling the controller C1 and controller C2, so these so signals are necessary for initiating the test,
- So BIST setup has to be 1 0 and MBISTPG_EN has to be 1
- BIST_SETUP will be controlled by BAP
- MBISTPG_EN will be going to the input of the controller.

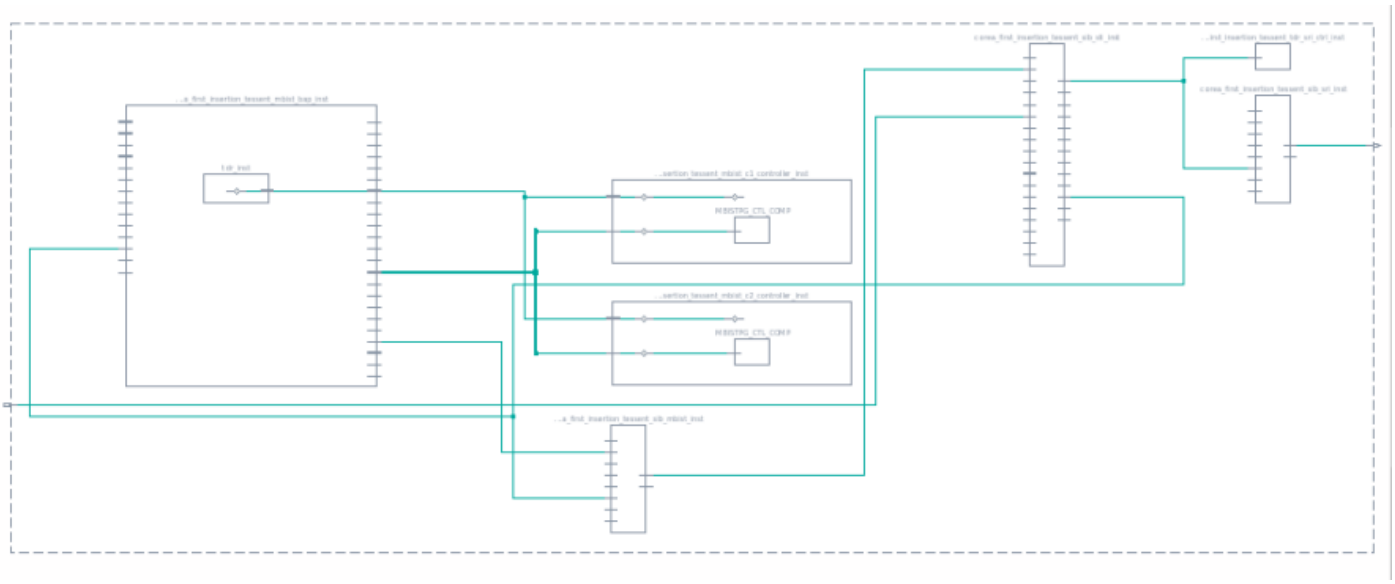


- BAP will be controlling 14 other signals.
- TDR which is present inside the BAP

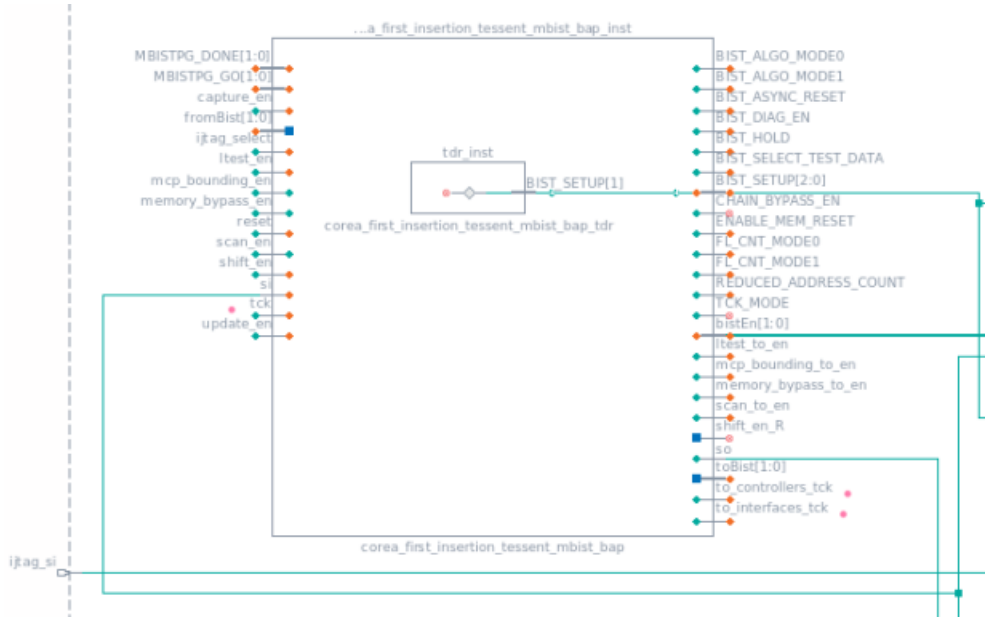


source schematic_ijtag_network.tcl to see it in the future purpose when we use it.

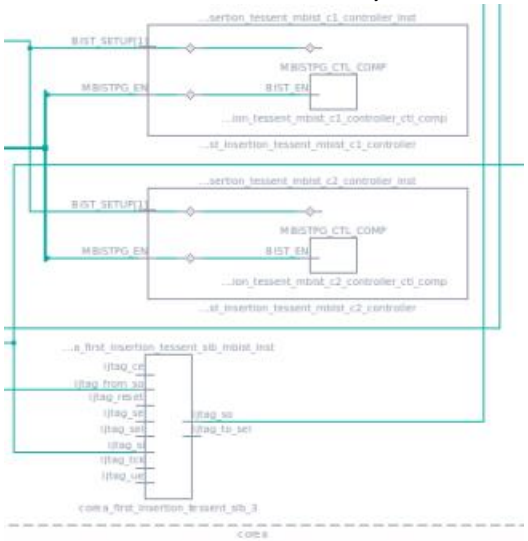
Hierarchical Schematic for COREA



1. **MBIST BAP**



2. **MBIST C1 and C2 Controllers, and MBIST SIB**



3. SIB STI, TDR SRI and SIB - 2

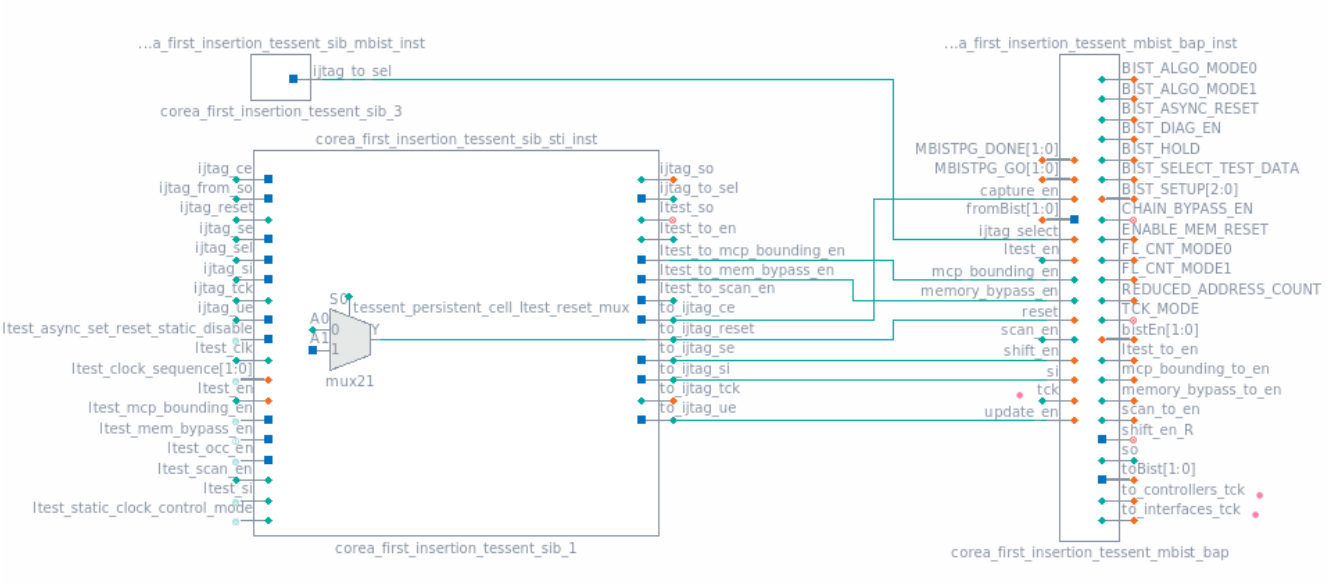
1. ICL File

Instrument Connectivity Language (ICL)

- Language used to describe test instruments and their access network.
- ICL is not a complete netlist. It only consists of abstract information required to navigate the instrument access network.

Interconnection between the components

```
Instance corea_first_insertion_tessent_mbist_bap_inst Of
    corea_first_insertion_tessent_mbist_bap {
   InputPort reset =
       corea_first_insertion_tessent_sib_sti_inst.to_ijtag_reset;
   InputPort ijtag_select =
       corea_first_insertion_tessent_sib_mbist_inst.ijtag_to_sel;
   InputPort si = corea_first_insertion_tessent_sib_sti_inst.to_ijtag_si;
   InputPort capture_en =
       corea_first_insertion_tessent_sib_sti_inst.to_ijtag_ce;
   InputPort shift_en =
       corea_first_insertion_tessent_sib_sti_inst.to_ijtag_se;
   InputPort update_en =
       corea_first_insertion_tessent_sib_sti_inst.to_ijtag_ue;
   InputPort tck = corea_first_insertion_tessent_sib_sti_inst.to_ijtag_tck;
   InputPort memory_bypass_en =
       corea_first_insertion_tessent_sib_sti_inst.ltest_to_mem_bypass_en;
   InputPort mcp_bounding_en =
       corea_first_insertion_tessent_sib_sti_inst.ltest_to_mcp_bounding_en;
   InputPort ltest_en =
       corea_first_insertion_tessent_sib_sti_inst.ltest_to_en;
   InputPort fromBist[1] =
       corea_first_insertion_tessent_mbist_c2_controller_inst.MBISTPG_SO;
   InputPort fromBist[0] =
       corea_first_insertion_tessent_mbist_c1_controller_inst.MBISTPG_SO;
   InputPort MBISTPG_GO[1] =
       corea_first_insertion_tessent_mbist_c2_controller_inst.MBISTPG_GO;
```



2. PDL File

Procedural Description Language (PDL)

- PDL provides a way to define procedures to operate an instrument.
- PDL is a sequence of commands that are a set of stimuli and expected responses that are applied on the interface of an instrument.
  - **iWrite :** Stimuli to the instrument are specified by iwrite.
    - Ex: iWrite Block1.MyTdr.R 8b00000101
      - In this example, the register R, an object in ICL instance MyTdr that is instantiated in instance Block1, is loaded with a value of 8b00000101
  - **iRead :** Expected responses are specified with the command iRead.
    - Ex: iRead Block1.MyTdr.R 0b0101
      - In this example, if R is an 8 bit wide register, then the compare value is zero padded to 0b00000101

- iWrite Block1.MyTdr.R 8b00000101
  The value (8b00000101) will be written onto this TDR (Block1.MyTdr.R)

- iRead Block1.MyTdr.R 0b0101
  The expected response (0b0101) is being specified by iRead command
  The value from this TDR (Block1.MyTdr.R) it should be this value (0b0101) which is expected value.

```
112   # [end]   : Setup Phase }}}
113   # [start] : Run phase {{{
114       set apply_run_phase yes
115     if { $apply_run_phase } {

173       iRelease ${controller_instance}.BIST_SETUP[1]
174     }
```

Go bit and Done bit should be zero

so before execution the starting of the test, the go bit and done bit has to be zero
Line 129: The iNote which is comments, so it is checking whether go bit fail before execution

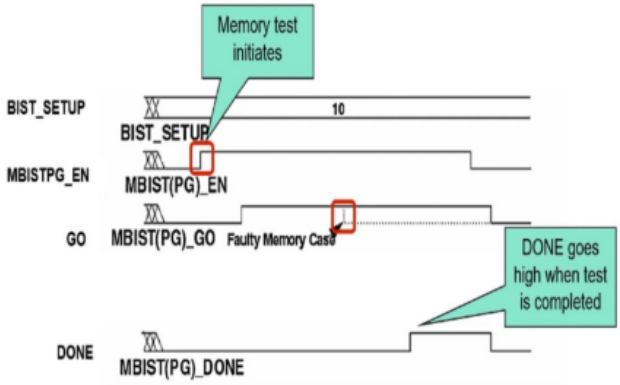
So iRead is fail then it has to be zero

And same goes for done so before execution done bit has to be zero

Line 140: iWrite - here we have to make MBISTPG_EN 1 only then the test will be starting

After MBIST is done, we are checking the go bits, the expected values of go and done bits should be 1
Go bit is 1 which means there is no error in the memory .
Done bit is 1 when the test is completed.

TESSENT MBIST OPERATING PROTOCOL



- Memory Test is initiated when MBISTPG_EN signal is high and 2 bits of BIST_SETUP is 10.
- If an error is found during test, the GO signal goes low and stays low during the remaining test.
- When the test is completed, the DONE signal goes high.

DONE	GO	
1	1	The memory BIST test ran to completion and passed
1	0	The memory BIST controller completed the test, but one of the memories being tested failed

- So before execution both go and done bit are zero, then the test is started go bit will be high and it will remain high till the test has completed, if no error is found
- If suppose if any faulty memory is there that is expected value and actual value
- Expected value which is written onto a comparator
- So the expected value and output from the memory if both are different that is faulty memory case then the go bit will go low and it will stay low during the remaining test and done bit it will be equal to high when the test is completed.
- Therefore, before execution both go and done bit should be zero … MBISTPG_EN will be made 1 and after execution go and done bit expected value should be 1

From line 131 and 137: iRead - Before execution we are checking whether go bit and done bit is failing where both are 0.

From line 140: iWrite - We are writing i.e. MBISTPG_EN to 1 where it should be made as 1.

From line 159 and 164: iRead - means this is the expected value, we are checking whether go bit and done bit has passed which is After execution.

3. SDC(Synopsys Design Constraints) File

- **In sdc file we will be having information about the clock, FP, MCP**

```
proc tessent_create_functional_clocks {} {

```

How the SIB has to operate here that is not available here? So where it will be available ?

- It will be available in instruments directory individually for all the SIBs, TDRs, controllers, BAP, verilog and ICL file.

So the tool will understand the functionality of the SIBs, TDRs, controller BAP, verilog and ICL file from taking information form the instruments directory.

65       MemoryBist_P1_configuration
66 if [ $? != 0 ] ; then xitval=-1; fi
67
68 if [ $xitval -ne 0 ]; then
69   echo "Simulation failed"
70 fi
71
72 exit $xitval
```

Here the tool is doing the TB file, IP file while giving the command only it is keeping it
Instead of keeping it in a file verilog file.list
It is directly keeping while giving a vlog command itself
So the script will automatically written by tool, tool is automatically writing this

- Instead of keeping verilog log file.list it will directly read during the vlog command.
- And vlog sim command it will directly reading the TB file.

So in corea.v only module instantiation will be there from line 19

And module def will be there in Entry 3 and Entry 4

In Entry 5, tool is reading the TB file(MemoryBist_P1.v) inside the patterns directory

Line 64: run -all, it will be done with simulations

So go to the questa.simulation_log file to check whether it is passing or failing

```
# 8600ns:  Enabling reduced address simulation
# 8600ns:  Enabling reduced address simulation
# 26000ns:  Checking GO is FAIL before execution
# 26000ns:  Checking DONE is FAIL before execution
# 26000ns:  Starting MemoryBist controller execution : corea_first_insertion_tessent_mbist_c1_controller_inst
# 26000ns:  Checking GO is FAIL before execution
# 26000ns:  Checking DONE is FAIL before execution
# 26000ns:  Starting MemoryBist controller execution : corea_first_insertion_tessent_mbist_c2_controller_inst
# 50300ns:  Checking GO is PASS after execution completion
# 50300ns:  Checking DONE is PASS after execution completion
# 50300ns:  Checking GO is PASS after execution completion
# 50300ns:  Checking DONE is PASS after execution completion
# 55900ns:  Checking GO_ID bits are PASS
# 55900ns:  Checking GO_ID bits are PASS
#
# Simulation finished at time 71901
# Number of miscompares            =          0
# Number of 0/1 compares           =        181
# Number of Z compares             =          0
```

Go to patterns directory

2. From ICLnetwork.Simulation

```
# Entry 5
vlog -work dut_work -L dut_work -mixedansiports +librescan  -ysearchlib -mfcu \
      "./patterns_directory/ICLNetwork.v" \
      -f questa.arguments_2
if [ $? != 0 ] ; then xitval=-1; echo "Failure on entry 5"; fi

# Entry 6
vlog -work dut_work -L dut_work -mixedansiports +librescan  -ysearchlib -mfcu \
      "./patterns.configuration"
if [ $? != 0 ] ; then xitval=-1; echo "Failure on entry 6"; fi

if [ $xitval -ne 0 ]; then
  echo "Compilation failed"
  exit $xitval
fi

vsim -c -lib "dut_work" -L dut_work -do 'run -all; exit' +nowarnTFMPC +NEWPATH=./patterns_directory \
      ICLNetwork_configuration
if [ $? != 0 ] ; then xitval=-1; fi

if [ $xitval -ne 0 ]; then
  echo "Simulation failed"
fi

exit $xitval
```

From MBIST Insertion, it will read the TB of MBIST TB but in ICLNetwork tool will be reading the ICLNetwork testbench i.e. (ICLNetwork.v) and other than that everything will remain unchanged.

```
# Simulation finished at time 13401
# Number of miscompares            =          0
# Number of 0/1 compares           =         64
